**Enhanced semi-automated mechanical transmission system.**

A control system (104)/method for semi-automatically executing manually or automatically selected upshifts and downshifts of a mechanical transmission system (10) is provided. The control system includes a central processing unit (106) for receiving input signals indicative of transmission input shaft (16) and output shaft (90) speeds and from a driver control console (108) indicative of selection of upshifts or downshifts from a currently engaged gear ratio and processing the same in accordance with predetermined logic rule to issue command output signals to a transmission actuator (112, 70, 96) and to a non-manually operable master friction clutch operator (CC) to implement a shift into transmission neutral and then the selected shifts upon a manual substantial synchronization of the transmission.

## BACKGROUND OF THE INVENTION

### Field of the Invention

This invention relates to vehicular semi-automatic mechanical transmission systems and, in particular, to semi-automatic mechanical transmission systems of the type providing partially automatic implementation of a manually or automatically selected shifting of mechanical transmission gear ratios. Transmission systems of this type are disclosed in U.S. Patent Nos. 5,053,961 and 5,053,962, both assigned to the assignee of this application, the disclosures of which are incorporated herein by reference. More particularly, the present invention relates to a semi-automated transmission system of the type described which is provided with a clutch actuator controlled by the system control unit.

### Description of the Prior Art

Fully automatic transmission systems, both for heavy-duty vehicles such as heavy-duty trucks, and for automobiles, that sense throttle openings or positions, vehicle speeds, engine speeds, and the like, and automatically shift the vehicle transmission in accordance therewith, are well known in the prior art. Such fully automatic change gear transmission systems include automated transmissions wherein pressurized fluid is utilized to frictionally engage one or more members to other members or to a ground to achieve a selected gear ratio as well as automated mechanical transmissions utilizing electronic and/or pneumatic logic and actuators to engage and disengage mechanical (i.e. positive) clutches to achieve a desired gear ratio. Examples of such transmissions may be seen by reference to U.S. Pat. Nos. 3,961,546; 4,081,065 and 4,361,060, the disclosures of which are hereby incorporated by reference.

Such fully automatic change gear transmissions can be unacceptably expensive, particularly for the largest heavy-duty vehicles which are not typically sold in high volumes. Additionally, those automatic change gear transmissions utilizing pressurized fluid and/or torque converters tend to be relatively inefficient in terms of power dissipated between the input and output shafts thereof.

Semi-automatic transmission systems utilizing electronic control units which sense throttle position, engine, input shaft, output shaft and/or vehicle speed, and utilize automatically controlled fuel throttle devices, gear shifting devices and/or master clutch operating devices to substantially fully automatically implement operator manually selected transmission ratio changes are known in the prior. Examples of such semi-automatic transmission systems may be seen by reference to U.S. Pat. Nos. 4,425,620; 4,631,679 and 4,648,290, the disclosures of which are incorpo-

rated herein by reference.

While such semi-automatic mechanical transmission systems are very well received as they are somewhat less expensive than fully automatic transmission systems, allow manual clutch control for low speed operation and/or do not require automatic selection of the operating gear ratio, they may be too expensive for certain applications as a relatively large number of sensors and automatically controllable actuators, such as a master clutch and/or a fuel throttle device actuators, are required to be provided, installed and maintained.

A semi-automatic shift implementation system/method for a mechanical transmission system for use in vehicles having a manually only controlled engine throttle means, and a manually only controlled master clutch is disclosed in above-mentioned U.S. Patent Nos. 5,053,961 and 5,053,962. This system includes a control/display panel or console for operator selection of upshifts, downshifts or shifts into neutral, an electronic control unit (ECU) for receiving input signals indicative of transmission input and output shaft speeds and of manually selected shifts and for processing same in accordance with predetermined logic rules to issue command output signals and a transmission actuator for shifting the transmission in accordance with the command output signals.

The control/display device will allow the operator to select/preselect a shift into a higher ratio, a lower ratio or into neutral and preferably will display the selected but not yet implemented shift as well as the current status of the transmission. Preferable the control will also allow selection of operation in an automatic preselection mode of operation.

Accordingly, a control system/method for a vehicular semi-automatic mechanical transmission system for partially automatic implementation of driver and/or controller selected transmission shifts which did not require throttle or clutch actuators, and which required only two speed signal inputs, was provided. While this type of transmission system was well received, for certain situations to enhance ease of operation, especially for less skillful drivers, the lack of an automated clutch controller to provide an automatic torque break and/or clutch start-from-stop engagement function was not totally satisfactory.

### SUMMARY OF THE INVENTION

In accordance with the present invention, the drawbacks of the prior art semi-automated transmission systems are overcome by the provision of a semi-automated transmission system wherein torque breaks to allow disengagement of a currently engaged gear ratio and/or clutch engagements at vehicle start-from-stop conditions are automatically implemented.

The above is accomplished by providing a semi-

automated transmission system of the general type described in above-mentioned U.S. Patents Nos. 5,053,961 and 5,053,962 with an actuator for selectively engaging and disengaging the vehicle master clutch. The master clutch actuator is controlled by command output signals from the system control unit.

Accordingly, is an object of the present invention to provide a new and improved semi-automated mechanical transmission system.

This and other objects and advantages of the present invention will become apparent from a reading of the detailed description of the preferred embodiment taken in connection with the attached drawings.

### BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a schematic illustration of the vehicular mechanical transmission system partially automated by the system of the present invention.

Figure 1A is a schematic illustration of the shift pattern of the transmission of Figure 1.

Figure 2 is a schematic illustration of the semi-automatic shift implementation system for a mechanical transmission system of the present invention.

Figure 3 is a schematic illustration of an alternate control console for the system of Figure 2.

### DESCRIPTION OF THE PREFERRED EMBODIMENT

Certain terminology will be used in the following description for convenience in reference only and will not be limiting. The words "upwardly", "downwardly", "rightwardly", and "leftwardly" will designate directions in the drawings to which reference is made. The words "forward", "rearward", will refer respectively to the front and rear ends of the transmission as conventionally mounted in a vehicle, being respectfully from left and right sides of the transmission as illustrated in Figure 1. The words "inwardly" and "outwardly" will refer to directions toward and away from, respectively, the geometric center of the device and designated parts thereof. Said terminology will include the words above specifically mentioned, derivatives thereof and words of similar import.

The term "compound transmission" is used to designate a change speed or change gear transmission having a multiple forward speed main transmission section and a multiple speed auxiliary transmission section connected in series whereby the selected gear reduction in the main transmission section may be compounded by further selected gear reduction in the auxiliary transmission section. "Synchronized clutch assembly" and words of similar import shall designate a clutch assembly utilized to nonrotatably couple a selected gear to a shaft by means of a positive clutch in which attempted engagement of

said clutch is prevented until the members of the clutch are at substantially synchronous rotation in a relatively large capacity friction means are utilized with the clutch members and are sufficient, upon initiation of a clutch engagement, to cause the clutch members and all members rotating therewith to rotate at substantially synchronous speed.

The term "upshift" as used herein, shall mean the shifting from a lower speed gear ratio into a higher speed gear ratio. The term "downshift" as used herein, shall mean the shifting from a higher speed gear ratio to a lower speed gear ratio. The terms "low speed gear", "low gear" and/or "first gear" as used herein, shall all designate the gear ratio utilized for lowest forward speed operation in a transmission or transmission section, i.e., that set of gears having the highest ratio of reduction relative to the input shaft of the transmission.

A "selected direction" of shifting will refer to selection of either single or multiple upshifting or downshifting from a particular gear ratio.

Referring to Figure 1, a range type compound transmission 10 of the type partially automated by the semi-automatic mechanical transmission system of the present invention is illustrated. Compound transmission 10 comprises a multiple speed main transmission section 12 connected in series with a range type auxiliary section 14. Transmission 10 is housed within a housing H and includes an input shaft 16 driven by a prime mover such as diesel engine E through a selectively disengaged, normally engaged friction master clutch C having an input or driving portion 18 drivingly connected to the engine crankshaft 20 and a driven portion 22 rotatably fixed to the transmission input shaft 16.

The engine E is fuel throttle controlled by a manually controlled throttle device (not shown) and the master clutch C is manually controlled by a clutch pedal (not shown) or the like. An input shaft brake B, operated by overtravel of the clutch pedal, is preferably provided to provide quicker upshifting as is well known in the prior art.

Transmissions similar to mechanical transmission 10 are well known in the prior art and may be appreciated by reference to U.S. Patent Nos. 3,105,395; 3,283,613 and 4,754,665, the disclosures of which are incorporated by reference.

In main transmission section 12, the input shaft 16 carries an input gear 24 for simultaneously driving a plurality of substantially identical countershaft assemblies 26 and 26A at substantially identical rotational speeds. The two substantially identical countershaft assemblies are provided on diametrically opposite sides of mainshaft 28 which is generally coaxially aligned with the input shaft 16. Each of the countershaft assemblies comprises a countershaft 30 supported by bearings 32 and 34 in housing H, only a portion of which is schematically illustrated. Each of the

countershafts is provided with an identical grouping of countershaft gears 38, 40, 42, 44, 46 and 48, fixed for rotation therewith. A plurality of mainshaft gears 50, 52, 54, 56 and 58 surround the mainshaft 28 and are selectively clutchable, one at a time, to the mainshaft 28 for rotation therewith by sliding clutch collars 60, 62 and 64 as is well known in the prior art. Clutch collar 60 may also be utilized to clutch input gear 24 to mainshaft 28 to provide a direct drive relationship between input shaft 16 and mainshaft 28.

Typically, clutch collars 60, 62 and 64 are axially positioned by means of shift forks associated with the shift housing assembly 70, as well known in the prior art. Clutch collars 60, 62 and 64 may be of the well known acting nonsynchronized double acting jaw clutch type.

Shift housing or actuator 70 is actuated by compressed fluid, such as compressed air, and is of the type automatically controllable by a control unit as may be seen by reference to U.S. Pat. Nos. 4,445,393; 4,555,959; 4,361,060; 4,722,237 and 2,931,237, the disclosures of which are incorporated by reference.

Mainshaft gear 58 is the reverse gear and is in continuous meshing engagement with countershaft gears 48 by means of conventional intermediate idler gears (not shown). It should also be noted that while main transmission section 12 does provide five selectable forward speed ratios, the lowest forward speed ratio, namely that provided by drivingly connecting mainshaft drive gear 56 to mainshaft 28, is often of such a high gear reduction it has to be considered a low or "creeper" gear which is utilized only for starting of a vehicle under severe conditions and, is not usually utilized in the high transmission range. Accordingly, while main transmission section 12 does provide five forward speeds, it is usually referred to as a "four plus one" main section as only four of the forward speeds are compounded by the auxiliary range transmission section 14 utilized therewith.

Jaw clutches 60, 62, and 64 are three-position clutches in that they may be positioned in the centered, nonengaged position as illustrated, or in a fully rightwardly engaged or fully leftwardly engaged position by means of a shift lever 72. As is well known, only one of the clutches 60, 62 and 64 is engageable at a given time and main section interlock means (not shown) are provided to lock the other clutches in the neutral condition.

Auxiliary transmission range section 14 includes two substantially identical auxiliary countershaft assemblies 74 and 74A, each comprising an auxiliary countershaft 76 supported by bearings 78 and 80 in housing H and carrying two auxiliary section countershaft gears 82 and 84 for rotation therewith. Auxiliary countershaft gears 82 are constantly meshed with and support range/output gear 86 while auxiliary section countershaft gears 84 are constantly meshed

with output gear 88 which is fixed to transmission output shaft 90.

A two-position synchronized jaw clutch assembly 92, which is axially positioned by means of a shift fork (not shown) and the range section shifting actuator assembly 96, is provided for clutching either gear 86 to mainshaft 28 for low range operation or gear 88 to mainshaft 28 for direct or high range operation of the compound transmission 10. The "shift pattern" for compound range type transmission 10 is schematically illustrated in Figure 1A.

Range section actuator 96 may be of the type illustrated in U.S. Pat. Nos. 3,648,546; 4,440,037 and 4,614,126, the disclosures of which are hereby incorporated by reference.

Although the range type auxiliary section 14 is illustrated as a two-speed section utilizing spur or helical type gearing, it is understood that the present invention is also applicable to range type transmissions utilizing combined splitter/range type auxiliary sections, having three or more selectable range ratios and/or utilizing planetary type gearing. Also, any one or more of clutches 60, 62 or 64 may be of the synchronized jaw clutch type and transmission sections 12 and/or 14 may be of the single countershaft type.

For purposes of providing semi-automatic shift implementation operation of transmission 10, an input shaft speed sensor and an output shaft speed sensor 100 are utilized. Alternatively to output shaft speed sensor 100, a sensor 102 for sensing the rotational speed of auxiliary section countershaft gear 82 may be utilized. The rotational speed of gear 82 is, of course, a known function of the rotational speed of mainshaft 28 and, if clutch 92 is engaged in a known position, a function of the rotational speed of output shaft 90.

The semi-automatic shift implementation control system 104 for a mechanical transmission system of the present invention is schematically illustrated in Figure 2. Control system 104, in addition to the mechanical transmission system 10 described above, includes an electronic control unit 106, preferably microprocessor based, for receiving input signals from the input shaft speed sensor 98, from the output shaft speed sensor 100 (or, alternatively, the mainshaft speed sensor 102) and from the driver control console 108. The ECU 106 may also receive inputs from an auxiliary section position sensor 110.

The ECU is effective to process the inputs in accordance with predetermined logic rules to issue command output signals to a transmission operator, such as solenoid manifold 112 which controls the mainsection section actuator 70, the auxiliary section actuator 96 and the master clutch actuator CC, and to the driver control console 108.

The driver control console allows the operator to manually select a shift in a given direction or to neutral from the currently engaged ratio, or to select a semi-

automatic preselect mode of operation, and provides a display for informing the operator of the current mode of operation (automatic or manual preselection of shifting), the current transmission operation condition (forward, reverse or neutral) and of any ratio change or shift (upshift, downshift or shift to neutral) which has been preselected but not yet implemented.

Console 108 includes three indicator lights 114, 116 and 118 which will be lit to indicate that the transmission 10 is in a forward drive, neutral or reverse drive, respectively, condition. The console also includes three selectively lighted pushbuttons 120, 122, and 124 which allow the operator to select an upshift, automatic preselection mode or a downshift, respectively. A pushbutton 126 allows selection of a shift into neutral.

A selection made by depressing or pushing any one of buttons 120, 122, 124 or 126 and may be cancelled (prior to execution in the case of buttons 120, 124 and 126) by redepressing the buttons. As an alternative, multiple depressions of buttons 120 and 124 may be used as commands for skip shifts. Of course, the buttons and lighted buttons can be replaced by other selection means, such as a toggle switch and/or a toggle switch and light or other indicia member. A separate button or switch for selection of reverse may be provided or reverse may be selected as a downshift from neutral. Also, neutral may be selected as an upshift from reverse or as a downshift from low.

In operation, to select upshifts and downshifts manually, the operator will depress either button 120 or button 124 as appropriate. The selected button will then be lighted until the selected shift is implemented or until the selection is cancelled.

Alternatively, at a given engine speed (such as above 1700 RPM) the upshift button may be lit and remain lit until an upshift is selected by pushing the button.

To implement a selected shift, the manifold 112 is preselected to cause actuator 70 to be biased to shift main transmission section 12 into neutral. This is accomplished by the operator causing a torque reversal by manually momentarily decreasing and/or increasing the supply of fuel to the engine and/or disengaging the master clutch C. The clutch operator CC is effective to disengage the master clutch C automatically and relieve the operator from the obligation of manually causing a torque break. As the transmission is shifted into neutral, and neutral is verified by the ECU (neutral sensed for a period of time such as 1.5 seconds), the neutral condition indicia button 116 is lighted. If the selected shift is a compound shift, i.e. a shift of both the main section 12 and of the range section 14, such as a shift from 4th to 5th speeds as seen in Figure 1A, the ECU will issue command output signals to manifold 112 to cause the auxiliary section actuator 96 to complete the range shift after neutral is

sensed in the front box.

When the range auxiliary section is engaged in the proper ratio, the ECU will calculate or otherwise determine, and continue to update, an enabling range or band of input shaft speeds, based upon sensed output shaft (vehicle) speed and the ratio to be engaged, which will result in an acceptably synchronous engagement of the ratio to be engaged. As the operator, by throttle manipulation and/or use of the input shaft brake, causes the input shaft speed to fall within the acceptable range, the ECU 106 will issue command output signals to manifold 112 to cause actuator 70 to engage the mainsection ratio to be engaged. Preferably, the actuator will respond very quickly not requiring the operator to maintain the input shaft speed within the acceptable range for an extended period of time. To select a shift into transmission neutral, selection button 126 is pushed. Indicating light 116 will flash until the ECU confirms that neutral is obtained at which time the light 116 will assume a continuously lighted condition while the transmission remains in neutral.

If desired, to provide enhanced (smoother) shift quality, the clutch operator CC may also be used during engagement of the target gear ratio.

In the automatic preselection mode of operation, selected by use of lighted pushbutton 122, the ECU will, based upon stored logic rules, currently engaged ratio (which may be calculated by comparing input shaft to output shaft speed) and output shaft speed, determine if an upshift or a downshift is required and preselect same. The operator is informed that an upshift or downshift is preselected and will be semi-automatically implemented by a command output signal from ECU 106 causing either lighted pushbutton 120 or lighted pushbutton 124 to flash and/or an audible shift alert signal. The operator may initiate semi-automatic implementation of the automatically preselected shift as indicated above or may cancel the automatic mode by depression of pushbutton 122.

As an alternative, the neutral condition indication light 116 may be eliminated and neutral selection pushbutton 126 replaced by a lighted pushbutton.

An alternate driver control and display console 130 may be seen by reference to Figure 3. A joy stick 132 is movable against a resilient bias from its centered position to select upshifts, downshifts, a shift to neutral or the automatic preselect mode by movement up, down, leftward or rightward, respectively, as indicated. Indicia lights 134 and 136 are lighted to indicate an upshift or downshift, respectively, is preselected. Indicia lights 138 and 140, respectively, are lighted to indicate a vehicle forward or reverse, respectively, mode of operation. Indicia light 142 is steadily lighted to indicate a transmission neutral condition and is flashed to indicate a preselected but not yet confirmed neutral condition. Indicia light 144 is lighted to indicate system 104 is operating in the au-

tomatic preselection mode of operation.

As a possible further enhancement for ease of operation of the semi-automated transmission system of the present invention, the ECU 106 may be provided with sufficient inputs and logic rules to allow use of clutch operator CC to engage the master clutch during vehicle start-from-stop operation.

If utilized solely to break torque and/or enhance target gear engagement after substantial synchronization, the clutch operator CC may be simply a two position actuator to cause substantially unmodulated movement of the clutch C between the fully engaged and fully disengaged positions thereof. Clutch actuator of this type are known in the prior art as may be seen by reference to U.S. Patent No. 5,048,656. If, however, a start-from-stop clutch engagement function is to be provided, a more accurately controlled clutch actuator is required as well as more sophisticated clutch control logic.

Automated clutch operators and control logic therefor sufficient for start-from-stop clutch engagement are known in the prior art as may be seen by reference to U.S. Patents Nos. 4,081,065; 4,899,858 and 4,874,070, the disclosures of which are incorporated herein by reference.

Accordingly, it may be seen that a relatively simple and inexpensive semi-automatic shift implementation control system (104)/method for a mechanical transmission system 10 requiring only a transmission shift actuator (112/70/96), a simple clutch operator CC and two rotational speed inputs (98/100) to be added to vehicle mechanical transmission system is provided. An electronic control unit 106 for receiving the two speed inputs, and inputs from an operator's console and for issuing command outsignals to the actuators and to the display portion of the operator's console is also provided. The system semi-automatically executes manually or automatically pre-selected shifts requiring the operator to cause substantially synchronous rotation for engagement of the selected mainsection ratio, which allows the system to operate without requiring automatically operated throttle controls.

Although the present invention has been described with a certain degree of particularity, it is understood that various changes to form and detail may be made without departing from the spirit and the scope of the invention as hereinafter claimed.

## Claims

**Claim 1.** A control system (104) for semi-automatic implementation of selected shifts of a mechanical change gear transmission system comprising a manually controlled fuel throttle controlled engine (E), a multi-speed change gear mechanical transmission (10), a master friction clutch (C) drivingly

interposed between the engine and the transmission, a non-manually controllable master clutch operator (CC) for engaging and disengaging said master clutch, a first sensor (98) for providing a first input signal indicative of transmission input shaft (16) rotational speed, a second sensor (100) for providing a second input signal indicative of the rotational speed of a transmission shaft (90) independently rotatable relative to the transmission input shaft under at least certain transmission operating conditions and a non-manually controllable transmission actuator (112, 70, 96) for controlling shifting of the transmission, said control system including;

means (120, 124/132) for selecting an upshift or a downshift from a currently engaged transmission ratio or from neutral to a selected ratio, and providing a third input signal indicative of said selection; and

a central processing unit (106) for receiving said first, second and third input signals and for processing same in accordance with predetermined logic rules to issue command output signals, said central processing unit including;

(a) means responsive to selection of a transmission shift from a currently engaged ratio for issuing command output signals to said actuator to bias the transmission to be shifted into neutral; and to said clutch operator to momentarily disengage said master clutch; and

(b) means responsive to (i) a selection of a shift from a currently engaged ratio into a selected ratio and (ii) confirmation of a transmission neutral condition for (i) sensing manual substantial synchronization of the transmission and (ii) thereafter for issuing command output signals to said actuator to cause the transmission to be shifted into the selected ratio.

**Claim 2.** The control system of claim 1 further comprising a manually operable master friction clutch operator, each of said clutch operators operable to selectively disengage said master friction clutch regardless of the position of the other of said clutch operators.

**Claim 3.** The control system of claim 1 wherein said selected shifts are manually selected.

**Claim 4.** The control system of claim 1 wherein said selected shifts are automatically selected.

**Claim 5.** A control method for controlling semi-automatic implementation of selected shifts of a semi-automatic mechanical change gear transmission system (104) comprising a manually controlled fuel throttle controlled engine (E), a multiple speed change gear mechanical transmission (10), a master friction clutch drivingly interposed between the engine and the transmission, a non-manually controllable master clutch operator (CC) for engaging and disengaging said master clutch, a first sensor (98) for providing an input signal indicative of the transmission input shaft (16) rotational speed, a second sensor (100) for pro-

viding an input signal indicative of the rotational speed of a transmission shaft (90) independently rotatable relative to the input shaft under at least certain transmission operating conditions, a non-manually controllable actuator (70/96) for controlling shifting of the transmission, a driver control console (108) including means (120, 124/132) for manually selecting an upshift or a downshift from a currently engaged ratio or neutral to a selected ratio and to provide an input signal indicative of same, and a central processing unit (106) for receiving said input signals and for processing same in accordance with predetermined logic rules to issue command output signals, said method characterized by:

- (a) responding to sensed selection of a shift from a currently engaged ratio by issuing command output signals to said actuator to bias the transmission to be shifted into neutral and to said clutch operator to momentarily disengage said master clutch; and
- (b) responding to (i) a sensed selection of a shift from a currently engaged ratio into a selected ratio and (ii) confirmation of a transmission neutral condition by (i) sensing manual substantial synchronization of the transmission and (ii) thereafter issuing command output signals to said transmission actuator to cause the transmission to be shifted into the selected ratio.

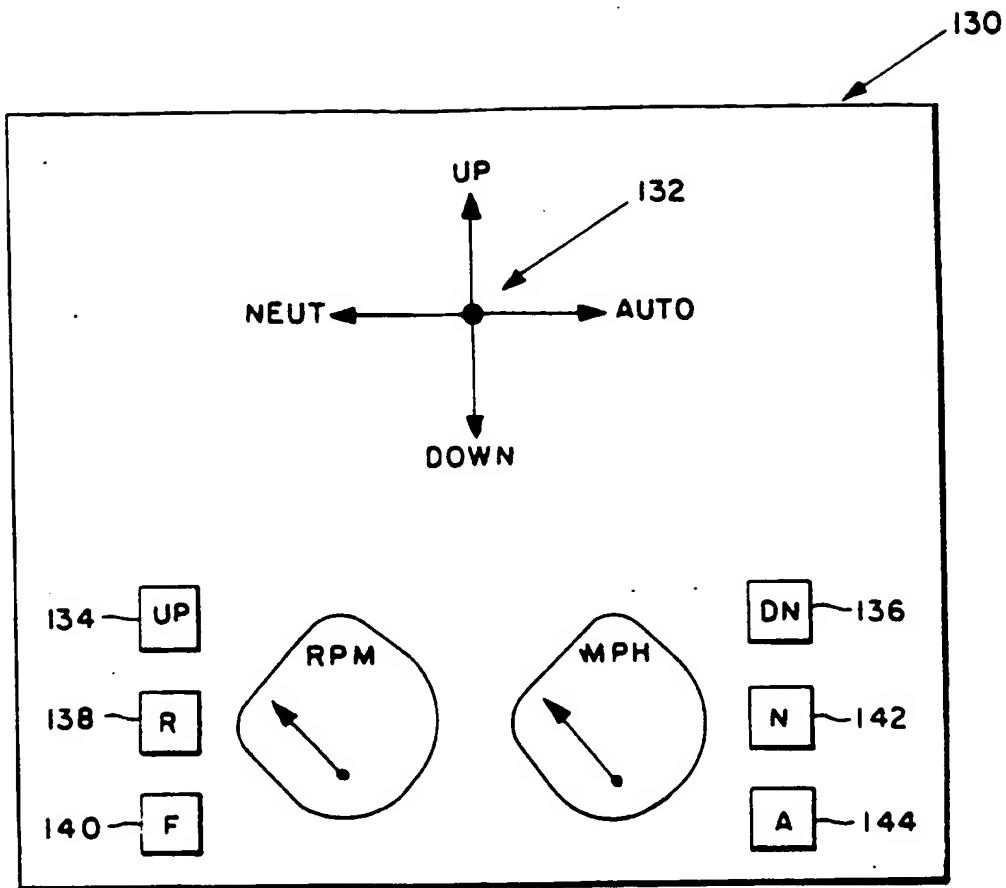

Claim 6. The control method of claim 5 further comprising a manually operable master friction clutch operator, each of said clutch operators operable to selectively disengage said master friction clutch regardless of the position of the other of said clutch operators.

Claim 7. The control method of claim 5 wherein said selected shifts are manually selected.

Claim 8. The control method of claim 5 wherein said selected shifts are automatically selected.
